

Selene

A privacy-first Solana wallet on mobile — your keys never touch the phone.

Solana Track (\$100K/10) · Crypto World's Fair · Native Android + APK

THE PROBLEM

The next billion users arrive on mobile with a wallet already in their pocket. But phones are the weakest custody surface — seed phrases leak, keychains get scraped. The best wallet is the one you don't have to think about.

WHAT IT IS

Self-custody Solana wallet built on the **Solana Mobile Stack** with **Mobile Wallet Adapter**, Jetpack Compose, Kotlin. Every transaction is authorized inside your existing MWA wallet (Phantom, Solflare, Solana Seeker) over a secure local WebSocket — Selene sends unsigned payloads and receives signed txs. No seed, no private key, no keystore on disk.

FEATURES (IMPLEMENTED)

Feature	Implementation
MWA connect	LocalAssociationScenario — local WebSocket session, association intent, 90s grace window
SOL approvals	Legacy tx compiled in-app, authorized via wallet's signAndSendTransactions
USDC (SPL) transfers	Token Program v3 transfer, accounts resolved via getTokenAccountsByOwner
Auto token-account creation	Recipient without USDC account → ATA created on the fly (PDA derivation + create + transfer in one byte-exact legacy message)

WHY WE WIN

- **Native Solana Mobile Stack, not a wrapper:** real MWA LocalAssociationScenario, real SPL transfers, real ATA creation — the exact primitives the Solana track rewards.
- **Shipping APK:** installable debug build (16.1 MB) — judges run it, they don't read about it.
- **Privacy is the point:** no telemetry, no analytics, no remote config — only your wallet and the public RPC.
- **Double eligibility:** also mobile-first fit for the Robinhood Chain track and the general pool.
